A person behind every agent payment.

Identity-backed permission.
On-chain limits. A human stop button.

HackMeridian 2026 · Innokenty Bodrov · Stellar testnet prototype

The problem

A wallet key cannot explain what a person authorized.

The owner asks

Who is acting for me?
Which merchant can they pay?
How much, and until when?

The application asks

Was the payment actually settled?
Is this a retry of the same invoice?
Can the owner stop the next payment?

Initial customer hypothesis: builders of agent-operated API purchases and merchant workflows. No traction claim.

The product

Four distinct boundaries. One understandable flow.

Verify

Didit confirms the existing identity.

Authorize

The demo owner signs exact spending terms.

Pay

Stellar enforces policies and settles value.

Revoke

The owner removes the permission.

Identity alone does not grant spending rights. An approval message alone is not a payment receipt.

Stellar integration

Compose identity, account policies and settlement.

OpenZeppelin on Soroban

- Smart account + Ed25519 verifier
- Rolling spending policy
- Custom merchant / per-payment policy

Execution and evidence

- Stellar SDK + CLI / WASM build
- Native XLM through its asset contract
- Durable invoice journal + original hash

Didit is the external identity layer. Proposed fit: Genesis / Stellar Composed; recorded portal selection and eligibility require confirmation.

What the demo proves

Valid payments settle.
Requests outside permission stop.

Scenario	Observed result
Signed permission: one merchant, 2 XLM / payment, 5 XLM total	**Installed on testnet**
1 + 2 + 1 XLM	**Three confirmed receipts**
Repeat the first invoice	**Same receipt; no second transfer**
Over 2 XLM / wrong merchant / over total budget	**Rejected before broadcast**
Revoke, then reload the page	**Rule removed; payment disabled**

Negative balance checks and network receipts retained

Engineering evidence

Test the failures.
Keep the original transaction.

58	Node checks pass
16	Signed Soroban host scenarios

Real-browser testnet acceptance

Timeouts reconcile by the saved hash. They do not create another envelope.

Live testing exposed credentials V2 and a status snapshot race. Both received failing regressions and fixes.

Local invoice idempotency is not global on-chain invoice uniqueness.

Progress and disclosure

Prepared foundations.
A working integration during the event.

Before 25 October

14 Oct: local signed-envelope prototype.

24 Oct: OpenZeppelin contracts and local harness.

25–26 October

Didit, wallet binding and explicit consent.

Durable invoice journal, real testnet deployment and settlement.

English UI and browser acceptance of positive, negative and revocation flows.

Prework is disclosed. We do not claim every line was built during the event or that prework scoring has been approved.

Make agent spending something a person can bound.

Next: external-wallet signatures, multi-user custody and authentication, credential revocation, stablecoins and merchant API payments.

Today: a single-owner testnet demo with server-held demo keys. No production, fiat, autonomous LLM-agent or global biometric-uniqueness claim.
